Date: May 22, 2019

Project Title: Macroinvertebrate Data: 2017

## I) Abundance and Biomass Data

The 2017 macroinvertebrate data provided information on abundance and biomass data at the level of taxonomic groups. The taxonomic level data were reformatted, and aggregated across taxa groups for analysis by SCS. All descriptions and analyses below relate to this aggregated data.

There were 97 observations in the compiled, aggregated data for 2017. Print Out #1 represents a listing of the data. The variables included were: *site*, *RKM*, *year*, *abundance* and *biomass*. The recorded values for site were KR2, KR4, KR6, KR7, KR9, KR9.1, KR10, and KR10.5. Descriptions of all sites are given on the KTOI Web database site at <http://scsnetw.com/ktoi>. The dates ranged from mid-March to late October. A Julian date variable was also created from this date range. Each site was represented by five to six replications. As per recommendation of Charlie Holderman, all values were adjusted to represent response levels per meter square ( $\text{g}/\text{m}^2$  and  $\#/ \text{m}^2$  for biomass and abundance, respectively). No subsampling was present in the 2017 data.

## II) Summary Statistics for Abundance and Biomass

Computations were carried out separately for each site over all sample periods. Basic summary information for both the abundance and biomass data are presented in Print Out #2. The 8 sites varied widely in their minimum, mean, maximum and variance values. The number of observations ranged from 6 to 15. Large maximum abundances were noted at site KR9.1. The maximum biomass value at site KR9.1 was also very large.

A more detailed summary of each site is given in Print Out #3. Site KR2 in 2017, for example, had a mean abundance of 1690.35 with a sample size of 6. The variance was 1697351.49 and the standard error of the mean was 531.8. The skewness value, a measure of symmetry for the frequency distribution, was moderate at -0.05 indicating a slightly asymmetric distribution. Biomass for KR2 had a mean value of 0.94  $\text{g}/\text{m}^2$  with 6 observations. The variance was 1.19 and the standard error was 0.45  $\text{g}/\text{m}^2$ . Skewness for biomass was higher at 0.799. Further examination of the quantiles and frequency plots for abundance and biomass also indicate some skewness. Statistical tests for normality are significant for both response variables in KR2, thus, the hypothesis that the data originates from a symmetric normal distribution is rejected. Because sample size estimation and statistical inference assume normally distributed

data, a transformation of the data is required prior to further analysis. As was the case for previous years, the natural logarithm was chosen as a transformation to mitigate distributional skewness. Abundance and biomass for the remaining sites were also notably skewed, therefore, these data were also log transformed prior to analysis. This transformation was successful in mitigating the effects of the anomalous data values noted earlier. Summary information for the transformed data (referred to as L\_abun and L\_bio for abundance and biomass, respectively) are given in Print Out #4. All subsequent statistical analyses reported here will be based on the log transformed data.

## Trends Over Time and RKM

Plots of abundance and biomass trends for each site across date are given in Print Out #5. These plots provide both the mean trend and box plots for log transformed responses at each date. The box plots at each time indicate the spread of the data on each side of the mean. Only one sample date is available for site KR2 and KR4 and there are three dates for the remaining sites. These show variable trends, either increasing or decreasing, depending on site.

Print Out #6 gives abundance and biomass trends over RKM. While the variability is high for both responses, some trend is evident, where abundance and biomass values tend to show elevated values within the nutrient addition zone peaking at KR9.1 (RKM 276.1, denoted with vertical reference line). As in previous data sets, it is noted that sites KR2-KR4 (RKM 123-231) show consistently lower levels of abundance and biomass than sites KR9 and KR9.1 (RKM 262.2 and 276.1, respectively).

## III) Determination of Sample Sizes

The formulation for calculating sample size is given by:

$$n = (z^*s/d)^2$$

where s, d and z are related to the variability, desired precision, and confidence levels, respectively. For this analysis, sample sizes were evaluated at the confidence levels: 90, 95, and 99%. The measure of variability was obtained from the data at hand and the precision set to approximately 10% of the overall mean abundance value and 50% of the mean biomass value due to low response levels. Because of the logarithmic transformations used for abundance and biomass responses, this value may vary slightly. Sample size estimation was carried out separately for abundance and biomass at each site.

Estimated sample sizes for abundance and biomass are given in the Print Outs #7. For abundance, the sample sizes were small at all confidence levels, indicating that the current sampling scheme of 6 replications is sufficient for that response. Biomass sample sizes at 95% confidence for biomass were nominal for all but a few sites. Sites KR6, KR9, KR10, and KR10.5 had very large estimated sample sizes, primarily due to variance measures larger than their respective means or very small mean values, making the estimation of 10% of the mean value

difficult. This may be due to sampling error or naturally small mean biomass values at these sites. Overall, however, the current sampling scheme can be considered as providing a precision level at or below the desired levels.

Note that for all the above calculations, the resulting sample size values are preliminary and also based on limited data. Thus, care should be exercised in applying these results to setting policy regarding future sampling protocols.

#### **IV) Comparison of Years**

Print Out #8 presents the estimated sample sizes (at the 95% level of confidence) for abundance and biomass in all years 2003 - 2017. Missing values (“-”) in the tables are due to changes in the sites sampled across years.

Sample sizes for abundance are equivalent and adequate for all years indicating few changes over the 2003-2017 period. Biomass sample sizes are comparable for all sites except for KR6, KR9, KR10, and KR10.5, as noted above. Because the macroinvertebrate designation encompasses a large range of species and organism sizes, variability in the biomass response is inevitable. Computation of sample size estimates based on taxonomic classes such as species, family, functional group, etc., may provide more reliable information on the biomass response in the future. It is notable, however, that over the course of the project, sample size estimates have decreased and stabilized indicating less sample variability. This is indicative to improved sampling methods as well as better establishment and consistency of macroinvertebrate sampling protocols.

Plots of abundance and biomass over sites in the years spanning 2003-2017 are given in Print Out #9. On these plots, the nutrient addition site (KR9.1) is indicated with a vertical reference line. Both abundance and biomass show general trends similar to those of the preceding years, however, it is noted that the abundance response in 2017 was average in comparison to previous years. Similarly, while biomass showed an elevated response in the nutrient addition zone typical of the Post Nutrient Addition period, the overall pattern in the fertilization zone was somewhat larger than many past years. Lower river values were average, relative to all years. Annual changes in abundance or biomass trends may reflect actual fluxuations in the responses as well as sampling error due to changes and refinements in the sampling procedures, protocols, and personnel. Overall, however, the nutrient addition site, KR9.1, shows a continued elevation in response rates for 2017, as well as higher response levels than pre-nutrient addition years. This is also contrasted to the consistently lower responses at geographically similar sites KR10 and KR10.5, where no nutrient addition treatments have been applied.

## V) Additional Remarks

- The data provided to SCS for 2017 macroinvertebrates were recompiled for analysis. Additional information on family, taxa, etc., were not included in this report. The data provided was free from errors and missing values.
- The 2017 macroinvertebrate data have now been incorporated into the relational database as part of the KTOI Ecosystem Web site (<http://ktoi.scsnetw.com>).
- Responses in the nutrient addition sites, KR9 and KR9.1, in 2017 continue to show higher average abundance and biomass values over the years before nutrient addition began. In contrast, sites KR10 and KR10.5, just upriver from the nutrient addition site, consistently shows lower levels of these responses.
- Trend analysis and sample size estimates for abundance and biomass measurements may be improved with additional information on subgroups. Such Information may include species, ecological, functional, or taxonomic classifications.
- Any additional information regarding biological, ecological, environmental, or physical variables could enhance the estimation process. To be of maximum utility, these variables should be available for each site during all sampling periods. Examples of potentially useful variables might be air and water temperature, thermal or degree day measurements, stream velocity and discharge rates, and habitat or substrate information (cobble size, depth, embeddedness, etc.).
